

4.6 Survival strategies — convergence

How does allowing parents to survive affect solution quality over generations?

Target: flag_100.png | Budget: 300 generations | 50 triangles | Population: 30 | Selection: Elite | Crossover: One-point

Each colour is one configuration. Line = median across seeds; shading = middle 50% (IQR), not a confidence interval. Lower curves mean better solutions at that generation. n = number of runs; generation speed is not wall-clock speed. Current-generation best, not best-so-far: increases reveal lost quality; the median can hide losses in individual runs.
